**Abstract** Iterative methods for solving nonlinear least-squares problems are of great interest because of their unique structures and wide range of applications. This paper exploits the unique structure and proposes a quasi-Newton diagonal-based approximation for solving this class of problems. Under some appropriate conditions, the search direction satisfies the sufficiently descent condition, and the new method is shown to be globally convergent. The numerical efficiency of the new method is tested on some standard benchmark test problems. Subsequently, the new method is implemented to solve 2 dimensional robotic motion control problem.

## 1. INTRODUCTION

In this paper, we are concerned with iterative methods for solving the following nonlinear least squares (NLS) problem

$$\min_{x \in \mathbb{R}^n} f(x), \quad f(x) = \frac{1}{2} \|F(x)\|^2, \quad (1.1)$$

---

\*Corresponding author.

where  $F(x) = (F_1(x), F_2(x), \dots, F_m(x))^T$  and each residual  $F_i : \mathbb{R}^n \rightarrow \mathbb{R}$ ,  $i = 1, 2, \dots, m$ , is assumed to be twice continuously differentiable. The problem (1.1) is a special class of general unconstrained optimization problems. Let the Jacobian of the vector-valued function  $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$  ( $m \geq n$ ) be denoted by  $J(x)$  at  $x \in \mathbb{R}^n$ . The gradient  $\nabla f(x)$  and Hessian  $\nabla^2 f(x)$  of problem (1.1) are respectively denoted by  $g(x)$  and  $H(x)$  and are given by

$$g(x) := \sum_{i=1}^m F_i(x) \nabla F_i(x) = J(x)^T F(x), \quad (1.2)$$

$$H(x) := U(x) + V(x), \quad (1.3)$$

where  $U(x) = J(x)^T J(x)$ ,  $V(x) := \sum_{i=1}^m F_i(x) \nabla^2 F_i(x)$ , the real-valued function  $F_i$  represents the  $i$ th component of the vector-valued function  $F$  and  $\nabla^2 F_i(x)$  is its Hessian.

NLS problems have been of great interest to many researchers due to the special structure of their gradient and Hessian. A number of iterative methods for solving them have been developed and can be categorized into two, namely: (i) general unconstrained optimization methods that includes Newton's method and quasi-Newton methods; and (ii) special methods: these methods utilize the special structure of the problem, example of which includes Gauss-Newton method, Levenberg-Marquardt method and structured quasi-Newton methods (see, [1–5]). Detail of these methods can be found in the following surveys [6, 7]. On the other hand, the study of efficient method for NLS problems is important due to its appearance in many applications such as robotic motion control, data fitting, optimal control, parameter estimation, experimental design, data assimilation, and imaging problems (see, [8–22]). For example, the values for the parameters that best match the model of a given data set can be determined by minimizing the sum of the squares of the residuals.

It is a known fact that the nice structures of the gradient and Hessian of problem (1.1) are usually utilized to come up with efficient methods. For instance, based on a modified secant equation and the formula given in (1.2) and (1.3), Kobayashi et al. [23] proposed a class of conjugate gradient-like structured methods for solving problems in the form of (1.1). Also, Dehghani and Mahdavi-Amiri [24] proposed another conjugate gradient-like method for solving problem (1.1). They incorporated a modified secant equation into the method so as to get as much information of the Hessian of problem (1.1) as possible. For more on recently developed matrix-free structured methods, the interested reader may refer to the following references [25–27].

Motivated by the success of the work presented in [25], Mohammad and Santos [28] proposed a diagonal Hessian approximation method for solving problem (1.1). The entries of the diagonal matrix are calculated using some structured vectors derived in such a way that the secant condition is approximately satisfied. Their method works well and is shown to be numerically efficient. However, the authors commented on the need to further investigate better approximations of the Hessian matrix that utilize the special structure of problem (1.1). In this paper, we present a new method for solving problem (1.1) based on a structured diagonal matrix that approximate the Hessian of the objective function. Furthermore, we incorporate some diagonal correction matrix into the formula for calculating the entries of the diagonal matrix. We highlight some contributions of the propose method below:

- In building the structured diagonal matrix approximation of our method, we incorporated some diagonal correction matrix which will be updated as the iteration process progresses. By this, we expect our diagonal matrix to contain more information of the objective function than the one proposed in [28].
- Our proposed method generates descent directions and is globally convergent.
- We implement the algorithm of the new method without the need to explicitly compute any matrix throughout the iteration process.
- We present numerical experiments to demonstrate the efficiency of the new method.
- We successfully apply the new method to solve 2D robotic motion control problem.

We organized the remainder of this paper as follows. We present the proposed method and its algorithm in the next section and discuss the convergence analysis in Section 3. We give numerical experiments and subsequently apply the algorithm to the robotic motion control problem in Section 4. Throughout this article, we denote the Euclidean norm of vectors and the induced 2-norm of matrices by  $\| \cdot \|$ .

## 2. PROPOSED METHOD

An important concept of a structured quasi-Newton method for nonlinear least squares is the structure principle [29]. Now, let  $k = 1, \dots, n$ , and suppose that at certain iteration, say  $k - 1$ , the first term of the Hessian, (1.3), is given

$$U(x_{k-1}) = \sum_{i=1}^m \nabla F_i(x_{k-1}) \nabla F_i(x_{k-1})^T. \tag{2.1}$$

Setting  $s_{k-1} = x_k - x_{k-1}$  and applying Taylor’s expansion on  $F(x_{k-1})$ , we have

$$F_i(x_{k-1}) = F_i(x_k) - \nabla F_i(x_k)^T s_{k-1} + o(\|s_{k-1}\|), \tag{2.2}$$

where  $F_i(x)$  is the  $i^{th}$  component of the vector-valued  $F(x)$  and  $o : [0, +\infty) \rightarrow \mathbb{R}$  such that  $\lim_{e \rightarrow 0} \frac{o(e)}{e} = 0$ .

Truncating the last term of (2.2) and then multiply it by  $\nabla F_i(x_k)$  from the left, we have

$$\nabla F_i(x_k) [F_i(x_k) - F_i(x_{k-1})] \approx \nabla F_i(x_k) \nabla F_i(x_k)^T s_{k-1}. \tag{2.3}$$

Summing both sides of (2.3) for  $i = 1, \dots, m$ , we have

$$\sum_{i=1}^m \nabla F_i(x_k) [F_i(x_k) - F_i(x_{k-1})] \approx \sum_{i=1}^m \nabla F_i(x_k) \nabla F_i(x_k)^T s_{k-1}. \tag{2.4}$$

This means that the updating matrix  $U(x_k)$  of (2.1) satisfies

$$U(x_k) s_{k-1} \approx \hat{y}_{k-1}, \text{ where } \hat{y}_{k-1} = J_k^T (F(x_k) - F(x_{k-1})), J_k = J(x_k). \tag{2.5}$$

On the other hand, to approximate the second term  $V(x)$  of (1.3) at iteration  $k$ , we also apply the Taylor expansion on  $\nabla F_i(x_k)$  and the result is

$$\nabla^2 F_i(x_k) s_{k-1} = \nabla F_i(x_k) - \nabla F_i(x_{k-1}) + \bar{o}(\|s_{k-1}\|), \tag{2.6}$$

where for each  $i = 1, \dots, m$ , we have  $\bar{o} : [0, +\infty) \rightarrow \mathbb{R}^n$  satisfying  $\lim_{e \rightarrow 0} \frac{\bar{o}^i(e)}{e} = 0$ .

Again, truncating the last term of (2.6) and then multiply it with  $F_i(x_k)$  on the left yields

$$F_i(x_k)\nabla^2 F_i(x_k)s_{k-1} \approx F_i(x_k)[\nabla F_i(x_k) - \nabla F_i(x_{k-1})]. \tag{2.7}$$

Also, summing both sides of (2.7), for  $i = 1, \dots, m$ , gives

$$\sum_{i=1}^m F_i(x_k)\nabla^2 F_i(x_k)s_{k-1} \approx \sum_{i=1}^m F_i(x_k)[\nabla F_i(x_k) - \nabla F_i(x_{k-1})]. \tag{2.8}$$

This gives

$$V(x_k)s_{k-1} \approx \bar{y}_{k-1}, \text{ where } \bar{y}_{k-1} = (J_k - J_{k-1})^T F_k. \tag{2.9}$$

Let  $D_k = D(x_k)$ ,  $U_k = U(x_k)$  and  $V_k = V(x_k)$ . Suppose that the sum of the two square matrices  $U(x_k)$  and  $V(x_k)$  is approximated with a diagonal matrix  $D_k \approx U_k + V_k$ , such that the weak secant is satisfied, i.e.,

$$s_{k-1}^T D_k s_{k-1} = s_{k-1}^T y_{k-1}, \tag{2.10}$$

where

$$y_{k-1} = \hat{y}_{k-1} + \bar{y}_{k-1} = J_k^T (F(x_k) - F(x_{k-1})) + (J_k - J_{k-1})^T F_k. \tag{2.11}$$

Now, let  $D_0 = I$ , where  $I$  is an identity matrix, such that the diagonal matrix  $D_k$  can be updated as

$$D_k = D_{k-1} + \Omega_{k-1}, \quad k \geq 1, \tag{2.12}$$

where  $\Omega_{k-1}$  is a diagonal matrix. Observe that  $\Omega_{k-1}$  is the deviation between  $D_{k-1}$  and  $D_k$ . The diagonal matrix  $\Omega_{k-1}$  is a correction matrix of  $D_{k-1}$  such that  $D_k$  satisfies weak secant equation [30]. The update  $D_k$  will be constructed from  $D_{k-1}$  in such a way that a constrained minimization problem involving  $\|D_k - D_{k-1}\|$  and the trace of  $(D_{k-1} + \Omega_{k-1})$  is solved. The reason for integrating the trace of  $(D_{k-1} + \Omega_{k-1})$  into the optimization problem is to obtain a correction matrix  $\Omega_{k-1}$  which clusters the eigenvalues of  $D_k$  such that its condition number improves, subject to the constraint condition  $s_{k-1}^T D_k s_{k-1} = s_{k-1}^T y_{k-1}$ , with  $y_{k-1}$  given as in (2.11). The formula for calculating the entries of the diagonal correction matrix  $\Omega_{k-1}$  is given in the following Lemma. The proof of the Lemma can be obtained in [31].

**Lemma 2.1.** *Let  $D_{k-1}$  be a diagonal matrix, with diagonal entries  $d_{k-1}^i$ ,  $i = 1, 2, \dots, n$ . Then the diagonal matrix  $\Omega_{k-1}$ , with entries  $\omega_{k-1}^i$ , in the following constrained minimization problem*

$$\min_{\Omega} \frac{1}{2} \|\Omega_{k-1}\|_F^2 + tr(D_{k-1} + \Omega_{k-1}), \tag{2.13}$$

$$s.t \quad s_{k-1}^T (D_{k-1} + \Omega_{k-1}) s_{k-1} = r_{k-1}, \tag{2.14}$$

satisfies

$$\omega_{k-1}^i = \frac{(s_{k-1}^T s_{k-1} - s_{k-1}^T D_{k-1} s_{k-1} + r_{k-1})(s_{k-1}^i)^2}{\sum_{i=1}^n (s_{k-1}^i)^4} - 1, \tag{2.15}$$

where  $r_{k-1} = s_{k-1}^T y_{k-1}$  and  $y_{k-1}$  is given by (2.11). Also  $tr(\cdot)$  and  $\|\cdot\|_F$  represent trace of a matrix and Frobenius norm of matrix, respectively.

Let  $D_0 = \text{diag}(h_0^1, h_0^2, \dots, h_0^n)$ , where for each  $i = 1, \dots, n$ ,  $h_0^i = 1$ . Using the Lemma 2.1, the entries of the diagonal matrix (2.12) are calculated as follows

$$h_k^i = h_{k-1}^i + \omega_{k-1}^i, \quad k \geq 1, \tag{2.16}$$

where  $\omega_{k-1}^i$  is computed using (2.15).

### 2.1. SAFEGUARDING STRATEGY

To make sure that the diagonal matrix  $D_k$  is positive definite, in what follows, we present a safeguarding strategy to ensure each diagonal entry is strictly positive. This can be done by simply safeguarding the diagonal entries  $h_{k-1}^i + \omega_{k-1}^i$  from assuming negative values or zero. Now, let  $\ell > 0$  and  $0 << u << +\infty$ , we redefine the entries of the diagonal matrix  $D_k$  as follows

$$h_k^i = \min \{ \max \{ h_{k-1}^i + \omega_{k-1}^i, \ell \}, u \}, \tag{2.17}$$

with  $\omega_{k-1}^i$  given in (2.15) and  $h_0^i = 1$ , for each  $i$ . The main aim for introducing the parameter  $u$  is to prevent the diagonal entries from assuming extremely large values.

### 2.2. ALGORITHM OF THE PROPOSED METHOD

In this subsection, we present the algorithm of the proposed method. Let  $d_k$  and  $g_k$  be the search direction and the gradient of  $f$  at  $x_k$ , i.e.  $\nabla f(x_k)$ , respectively. Let  $x_0 \in \mathbb{R}^n$  be an initial guess, then the next point is calculated via

$$x_{k+1} = x_k + \alpha_k d_k, \quad k = 0, 1, 2, \dots \tag{2.18}$$

The search direction,  $d_k$  in (2.18) is obtained by solving the linear systems

$$D_k d_k = -g_k, \tag{2.19}$$

$$D_k = \begin{cases} I, & \text{if } k = 0, \\ \text{diag}(h_k^1, h_k^2, \dots, h_k^n), & \text{if } k \geq 1, \end{cases}$$

where  $h_k^i$ ,  $i = 1, 2, \dots, n$ , are computed using (2.17). We adopt the non-monotone line search of Zhang and Hager [32] to compute the step length  $\alpha_k$ . If the search direction  $d_k$  is descent, then the step length  $\alpha_k > 0$  in (2.18) should satisfy the following inequality

$$f(x_k + \alpha_k d_k) \leq P_k + \theta \alpha_k g_k^T d_k, \tag{2.20}$$

where

$$\begin{cases} P_0 = f(x_0), \\ P_{k+1} = \frac{\eta_k Q_k P_k + f(x_{k+1})}{Q_{k+1}}, \\ Q_0 = 1, \\ Q_{k+1} = \eta_k Q_k + 1, \end{cases} \tag{2.21}$$

and  $\theta \in (0, 1)$ ,  $\eta_k \in [0, 1]$ . We quickly note the following:

**Remark 2.2.**

- (i) The scalar  $P_{k+1}$  in (2.21) is a convex combination of  $P_k$  and  $f(x_{k+1})$ . Since  $P_0 = f(x_0)$ , it follows that the sequence  $\{P_k\}$  is a convex combination of the function values  $f(x_i)$ , for  $i = 0, 1, 2, \dots, k$ .

- (ii) The nonnegative parameter  $\eta_k$  commands the degree of monotonicity of the line search. If for each  $k$ ,  $\eta_k = 0$ , then the line search is the monotone Armijo-type line search; otherwise, it is nonmonotone.
- (iii) If the parameter  $\eta_k = 1$ , for all  $k$ , then  $P_k = \psi_k$  with  $\psi_k$  given as

$$\psi_k = \frac{1}{k+1} \sum_{i=1}^k f(x_i). \tag{2.22}$$

Next, we formally state the algorithm of the new proposed iterative method.

---

**Algorithm 1:** New Algorithm with Structured Diagonal Hessian (NASDH)

---

**Input :** Given  $x_0 \in \mathbb{R}^n$ ,  $\theta \in (0, 1)$ ,  $0 \leq \eta_{\min} \leq \eta_{\max} \leq 1$ ,  $\ell > 0$ ,  $0 << u << +\infty$ ,  $\epsilon > 0$ , and  $k_{\max} \in \mathbb{N}$ .

**Step 1:** Set  $k = 0$ ,  $D_k = I$ ,  $Q_k = 1$ . Compute  $F_k$ ,  $g_k$ ,  $f_k = \frac{1}{2} \|F_k\|^2$  and set  $P_k = f_k$ .

**Step 2:** If  $\|g_k\| \leq \epsilon$  and  $k \geq k_{\max}$ , stop. Else compute the search direction

$$d_k = -D_k^{-1} g_k. \tag{2.23}$$

**Step 3:** Calculate the step length using nonmonotone line search as follows. Set  $\alpha = 1$ , if

$$f(x_k + \alpha d_k) \leq P_k + \alpha \theta g_k^T d_k, \tag{2.24}$$

then  $\alpha_k = \alpha$ . Else, set  $\alpha = \alpha/2$  and test (2.24) again.

**Step 4:** Compute the next iterate using  $x_{k+1} = x_k + \alpha_k d_k$ .

**Step 5:** Set  $s_k = x_{k+1} - x_k$  and compute  $y_k = \hat{y}_k + \bar{y}_k$  using (2.11).

**Step 6:** Calculate the entries of  $\Omega_k$  using (2.15) where  $r_k = s_k^T y_k$ .

**Step 7:** Update the entries of the diagonal Hessian approximation  $D_{k+1}$  using (2.17).

**Step 8:** Determine  $\eta_k \in [\eta_{\min}, \eta_{\max}]$  using any suitable sequence between 0 and 1, then calculate  $Q_{k+1}$  and  $P_{k+1}$  using (2.21).

**Step 9:** Set  $k = k + 1$  and go to **step 2**.

---

**Remark 2.3.**

- (i) Although the vectors  $g_k$ ,  $\hat{y}_k$  and  $\bar{y}_k$  in Algorithm NASDH are in the form of matrix-vector products, we implemented the algorithm as matrix-free. This implementation is done by writing MATLAB code that computes the matrix-vector products without explicitly forming any matrix throughout the iteration process.
- (ii) Due to the fact that the Hessian approximation  $D_k$  is a diagonal matrix, its inverse  $D_k^{-1}$  is calculated by simply taking the reciprocal of each  $h_k^i$  ( $i = 1, 2, \dots, n$ ). This means that the product  $D_k^{-1} g_k$  is calculated as component-wise vector multiplications.

In what follows, we discuss the convergence results of the proposed method. The following assumptions will be useful in our discussion.

**Assumption 2.4.**

**A1.** The level set  $\Theta = \{x \in \mathbb{R}^n \mid f(x) \leq f(x_0)\}$  is bounded.

**A2.** The function  $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$ , and its Jacobian are Lipschitzian. That is, for all  $x, y \in \Theta$ , there exist some positive constants  $L_1 > 0$  and  $L_2 > 0$  for which

$$\|F(x) - F(y)\| \leq L_1 \|x - y\|, \text{ and} \tag{2.25}$$

$$\|J(x) - J(y)\| \leq L_2 \|x - y\|. \tag{2.26}$$

Using the inequalities (2.25) and (2.26), we have the following conclusions

$$\|g(x) - g(y)\| \leq l \|x - y\|, \|F(x)\| \leq \omega_1, \|J(x)\| \leq \omega_2 \text{ and } \|g(x)\| \leq \omega_3,$$

where  $l > 0, \omega_1 > 0, \omega_2 > 0$  and  $\omega_3 > 0$  are given constants.

### 3. CONVERGENCE ANALYSIS

In this section, we first show that the diagonal entries of the correction matrix  $\Omega_k$  given by (2.15) are bounded.

**Lemma 3.1.** Let the Assumption 2.4 holds and assume  $\|s_{k-1}\| \neq 0$ , for all  $k \geq 1$ . Then the diagonal correction matrix,  $\{\Omega_{k-1}\}$ , generated by Algorithm NASDH, where its entries are computed by (2.15), is bounded provided the following inequality

$$|r_{k-1}| \leq v \|s_{k-1}\|^2, \quad v > 0, \tag{3.1}$$

holds.

*Proof.* We only need to show that (3.1) holds and the rest of the proof will follow from Lemma 2.1 in [31]. Let  $y_{k-1}$  be defined by (2.11) and  $r_{k-1} = s_{k-1}^T y_{k-1}$ , then

$$\begin{aligned} |r_{k-1}| &= \|s_{k-1}^T (J_k^T (F_k - F_{k-1}) + (J_k - J_{k-1})^T F_k)\| \\ &\leq \|s_{k-1}\| (\|J_k^T (F_k - F_{k-1})\| + \|(J_k - J_{k-1})^T F_k\|) \\ &\leq \|s_{k-1}\| (\|J_k\| \|F_k - F_{k-1}\| + \|J_k - J_{k-1}\| \|F_k\|) \\ &\leq \|s_{k-1}\| (w_2 L_1 \|s_{k-1}\| + w_1 L_2 \|s_{k-1}\|) \\ &\leq v \|s_{k-1}\|^2, \end{aligned}$$

where  $v = w_2 L_1 + w_1 L_2$ . Therefore, the inequality (3.1) holds and the conclusion of the Lemma is true. ■

**Lemma 3.2.** Suppose that the Algorithm NASDH generates the sequence of search directions  $\{d_k\}$ , then we can find some constants, say  $m_1 > 0, m_2 > 0$ , such that the following inequalities hold

$$g_k^T d_k \leq -m_1 \|g_k\|^2, \tag{3.2}$$

$$\|d_k\| \leq m_2 \|g_k\|, \tag{3.3}$$

for all  $k \geq 0$ .

*Proof.* Let the diagonal entries of the Hessian approximation  $D_k$  be defined by (2.17). From (2.17), it holds that

$$\ell \leq \min \{ \max \{ h_{k-1}^i + \omega_{k-1}^i, \ell \}, u \} \leq u, \tag{3.4}$$

and therefore, by the Equation (2.23) we have

$$\begin{aligned}
 g_k^T d_k &= -g_k^T D_k^{-1} g_k \\
 &= -g_k^T h_k^{-1} g_k \\
 &= -\sum_{i=1}^n (g_k^i)^2 / \min \{ \max \{ h_{k-1}^i + \omega_{k-1}^i, \ell \}, u \} \\
 &\leq -(1/u) \sum_{i=1}^n (g_k^i)^2 \\
 &= -m_1 \|g_k\|^2,
 \end{aligned}$$

where  $m_1 = 1/u$ , and (3.2) holds.

Similarly, by the fact that the diagonal matrix is symmetric, for all  $k$ , we have

$$\begin{aligned}
 \|d_k\|^2 &= g_k^T D_k^{-2} g_k \\
 &= g_k^T h_k^{-2} g_k \\
 &= \sum_{i=1}^n (g_k^i / \min \{ \max \{ h_{k-1}^i + \omega_{k-1}^i, \ell \}, u \})^2 \\
 &\leq (1/\ell^2) \sum_{i=1}^n (g_k^i)^2 \\
 &= m_2 \|g_k\|^2,
 \end{aligned}$$

where  $m_2 = 1/\ell^2$  and hence the proof. ■

Now, by Lemma 3.1 and 3.2 together with the Proposition 1 in [28], we conclude that the new Algorithm NASDH is well-defined. The following result comes from Lemma 1.1 of [32].

**Lemma 3.3.** *Suppose the sequence  $\{x_k\}$  is generated by Algorithm NASDH and  $P_k$  and  $\psi_k$  are defined by (2.21) and (2.22), respectively, then for all  $k = 0, 1, 2, \dots$ , it holds that  $f(x_k) \leq P_k \leq \psi_k$ .*

**Lemma 3.4.** *Suppose the sequences  $\{x_k\}$  and  $\{d_k\}$  are generated by Algorithm NASDH such that the relation (3.2) holds, then  $f(x_k) \leq f(x_0)$ , for each  $k \geq 0$ . That is,  $\{x_k\} \subset \Theta$ , where  $\Theta$  is the level set.*

*Proof.* Let  $P_{k+1}$  be given as in Equation (2.21), then using  $Q_{k+1} = \eta_k Q_k + 1$ , together with (2.20) and (3.2) yield

$$\begin{aligned} P_{k+1} &= \frac{\eta_k Q_k P_k + f(x_{k+1})}{Q_{k+1}}, \\ &= \frac{(Q_{k+1} - 1)P_k + f(x_{k+1})}{Q_{k+1}}, \\ &\leq \frac{Q_{k+1} P_k + \alpha_k \theta g_k^T d_k}{Q_{k+1}}, \\ &\leq \frac{Q_{k+1} P_k - \alpha_k \theta m_1 \|g_k\|^2}{Q_{k+1}}, \\ &= P_k - \frac{\alpha_k \theta m_1 \|g_k\|^2}{Q_{k+1}} \\ &\leq P_k, \end{aligned}$$

where the last inequality holds by dropping the negative term in the preceding line. This means the sequence  $\{P_{k+1}\}$  is decreasing and since  $f_k \leq P_k$ , (see, Lemma 3.3), we have

$$f(x_{k+1}) \leq P_{k+1} \leq P_k \leq P_{k-1} \leq \dots \leq P_0 = f(x_0),$$

and the proof is complete. ■

The following Theorem shows that Algorithm NASDH converges. The proof of the Theorem follows from [32] and so, we omit it here.

**Theorem 3.5.** *Suppose that  $x_k$  is the algorithm generated by Algorithm NASDH. If the Assumption 2.4 holds, then*

$$\liminf_{k \rightarrow \infty} \|g_k\| = 0. \tag{3.5}$$

Moreover, if  $\eta_{\max} < 1$  then

$$\lim_{k \rightarrow \infty} \|g_k\| = 0. \tag{3.6}$$

#### 4. NUMERICAL EXPERIMENTS

In this section, numerical experiments are reported in order to assess the efficiency of the proposed Algorithm NASDH in comparison with Algorithm SDHAM proposed in [28]. Both algorithms, that is, NASDH and SDHAM are implemented in such a way that computation of any matrix is completely avoided. In the course of this experiment, seventeen large-scale test problems (see, Table 1) are solved using five different dimensions, i.e. 3000, 6000, 9000, 12000 and 15000. This gives a total of eighty two large-scale test problems solve for this experiment. In Table 1,  $P_i$  stands for problem  $i$  where  $i = 1, 2, \dots, 17$ . The parameters used for the implementation of both algorithms are as follows

- Algorithm NASDH:  $\eta_k = \frac{1}{\exp(k+1)^{(k+1)}}$  with  $\eta_{\min} = 0.1, \eta_{\max} = 0.85, \ell = 10^{-30}, u = 10^{30}$ ; and  $\theta = 0.00001$ .
- Algorithm SDHAM: All parameters are as presented in [28].

The two algorithms are coded in MATLAB R2019b and the device used for the experiments is a PC with intel Core(TM) i5-8250u processor with 4 GB of RAM and CPU 1.60 GHZ. The iteration process is terminated whenever  $\|g_k\| \leq 10^{-4}$ . On the other hand, failure, denoted by “\_”, is recorded when the number of iterations is greater than 1,000 and the stopping criterion mentioned above has not been satisfied.

The results of the experiment are presented in Tables 2-3, where NITER, NFVAL, NMVP, TIME and FVALUE denote the number of iterations, the number of function evaluations, the number of matrix-vector product, the CPU time in seconds (TIME), and the value of the objective function  $f$  at the solution. From the information presented in Tables 2-3, it can be seen that both algorithms are competitive. Interestingly, while Algorithm SDHAM failed in some instances, the new Algorithm NASDH solves all the test problems considered in this experiment successfully. The results reported in Tables 2-3 are summarized in Figures 1-3 with the aid of the performance profile of Dolan and Moré [33]. These figures show that the new Algorithm NASDH outperforms Algorithm SDHAM in terms of NITER, NFVAL and NMVP. Putting everything together, it can be seen that the new Algorithm NASDH works well and is efficient.

TABLE 1. List of test problems with references and starting points

Problems	Function name	Starting point
Large-scale		
P1	Penalty function I [34]	$(1/3, 1/3, \dots, 1/3)^T$
P2	Trigonometric function [35]	$(1, 1, \dots, 1)^T$
P3	Discrete boundary value [35]	$(\frac{1}{n+1}(\frac{1}{n+1} - 1), \dots, \frac{1}{n+1}(\frac{1}{n+1} - 1))^T$
P4	Linear function full rank [35]	$(1, 1, \dots, 1)^T$
P5	Problem 202 [36]	$(2, 2, \dots, 2)^T$
P6	Sine function [37]	$(1, 1, \dots, 1)^T$
P7	Exponential function I [34]	$(\frac{n}{n-1}, \dots, \frac{n}{n-1})^T$
P8	Exponential function II [34]	$(\frac{1}{n^2}, \frac{1}{n^2}, \dots, \frac{1}{n^2})^T$
P9	Logarithmic function [34]	$(1, 1, \dots, 1)^T$
P10	Trigonometric Exponential System [38]	$(0, 0, \dots, 0)^T$
P11	Extended Freudenstein and Roth [34]	$(6, 3, 6, 3, \dots, 6, 3)^T$
P12	Extended Powell singular [34]	$(-1, -1, \dots, -1)^T$
P13	Broyden tridiagonal function [35]	$(-\frac{5}{4}, -\frac{5}{4}, \dots, -\frac{5}{4})^T$
P14	Extended Himmelblau [39]	$(1, 1/n, 1, 1/n, \dots, 1, 1/n)^T$
P15	Function 27 [34]	$(100, 1/n^2, 1/n^2, \dots, 1/n^2)^T$
P16	Trigonometric logarithmic function [28]	$(1, 1, \dots, 1)^T$
P17	Linear full rank I [35]	$(1, 1, \dots, 1)^T$

#### 4.1. APPLICATION OF ALGORITHM NASDH IN MOTION CONTROL

In this subsection, we implement the Algorithm NASDH to solve a time-varying non-linear optimization (TVNO) called the real-time motion control problem of a 2-D planar robotic manipulator. This problem is described as follows:

Initially, we have a discrete-time kinematic formulation of the problem at certain position level, as given in [40], is

$$f(\theta(t_k)) = \psi_k, \tag{4.1}$$

where for notational simplicity, we set  $\theta_k = \theta(t_k) \in \mathbb{R}^2$  and it denotes the joint angle vector at time  $t_k$ ,  $k = 0, 1, 2, \dots$ . The function  $f$  in (4.1) is a kinematic mapping function

is solved at each computational time interval  $[t_k, t_{k+1})$ , where, the end-effector,  $\psi_k$ , is controlled to track the following Lissajous curve

$$\psi_{dk} = \begin{bmatrix} 1.5 + 0.2 \sin(t_k) \\ \frac{\sqrt{3}}{2} + 0.2 \sin(2t_k) \end{bmatrix}. \tag{4.4}$$

To experimentally perform the simulation, we initialize the joint angle vector,  $\theta_0 = [0, \frac{\pi}{3}]^T$  and set the rod’s length as  $l_i = 1$  for  $i = 1, 2$  where the task duration,  $t_f = 10s$  is partitioned into 200 equal parts.

It can be observed from Figure 4(a) that Algorithm NASDH effectively synthesized the robot trajectories and Figure 4(b) shows that the end effector model is fitted with the desired path that describes the trajectories of the end effector. Finally, we plot the residual errors obtained from the synthesized robot trajectories on both  $x - axis$  and  $y - axis$ . These are reported in Figure 4(c)–4(d). It can be seen that the errors on both axes are as low as  $10^{-5}$ . This shows the applicability of the proposed Algorithm NASDH.

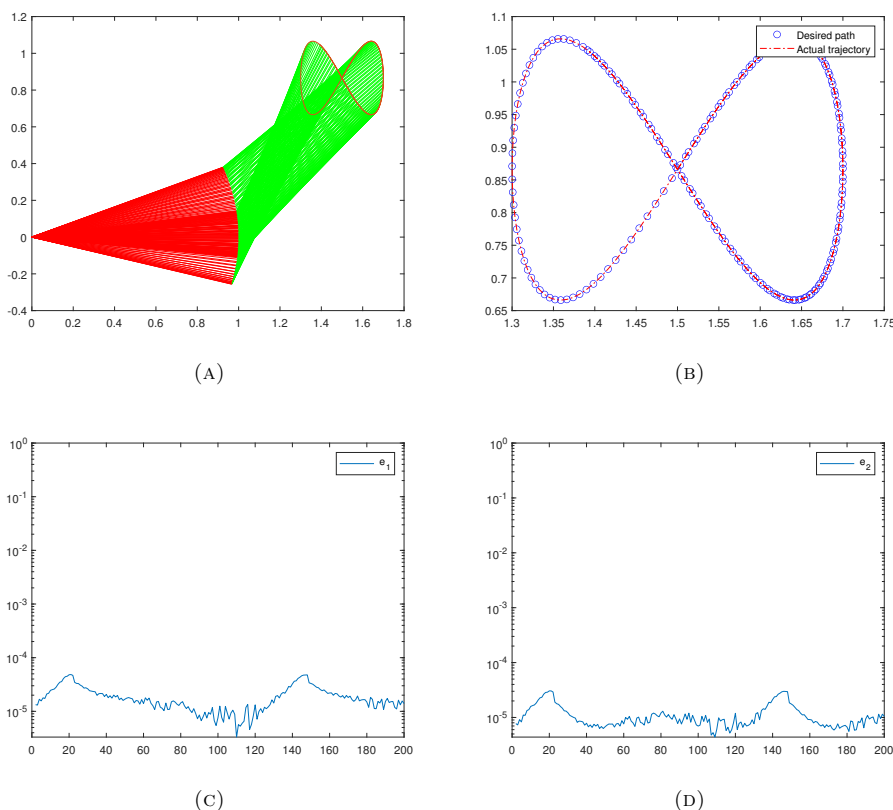

FIGURE 4. Numerical results generated in the course of robotic motion control experiment: (a) Robot trajectories synthesized by Algorithm NASDH. (b) End effector trajectory and desired path by Algorithm NASDH. (c) Residual error by Algorithm NASDH on x-axis. (d) Residual error by Algorithm NASDH on y-axis.

## 5. CONCLUSIONS

We have proposed an iterative method with an improved structured diagonal Hessian approximation for solving nonlinear least-squares problems. By incorporating some correction matrices into the sequence of our structured diagonal matrix approximation, it contains more information of the objective function than the one offered by Mohammad and Santos [28]. We coded the algorithm of the proposed method such that it neither form nor store matrices throughout the iteration process. This makes it suitable for large-scale problems. We have devised appropriate safeguards to ensure the diagonal entries are positive definite, which subsequently guaranteed that the search directions generated by the new method are sufficiently descending. We have presented numerical experiments on a collection of some benchmark test problems which showed the efficiency of the new method. Finally, we have implemented the Algorithm NASDH on problems arising from robotic motion control. Future work includes applying the new method to solve problems

arising from portfolio selection and data fitting. Furthermore, it will be interesting to use the idea in this paper to solve system of nonlinear equations and some applications [41–46].
